1 Introduction

The purpose of this document is to provide a quick and accessible understanding of the roll and tilt mechanism of SHER-3.0 (Eye Robot 3.0). It is assumed that the reader is already familiar with some basic engineering kinematics, robotics, and linear algebra concepts. A separate document covering the kinematic derivation of the delta platform is also available at https://github.com/zhaob5/delta_kinematics. If you haven't read it yet, **I strongly encourage you to review it** before diving into this document, as some explanations here build upon concepts introduced there. Some related papers and scripts can be found on this github page: https://github.com/zhaob5/roll_tilt_mechanism

2 System Overview

The base of SHER-3.0 is a delta mechanism, which has been described in detail in my previous work. Mounted on top of the delta stage is a 2-DOF arm with roll and tilt functionality. The tilt mechanism was designed with a four-bar linkage configuration, as illustrated in Fig.(1) and Fig.(2).

Figure 1: CAD models of the 5-DOF delta and roll-tilt mechanism

2.1 Tilting Mechanism

The structure of the tilt mechanism is depicted in Fig.(2). The joints A, B, C and D form a four-bar linkage mechanism. The joints A and B are fixed to the robot arm. This mechanism is actuated by an offset slider-crank mechanism with joints R, Q and A, where joint R is moved by a linear actuator. The rigid three-joint link QAD transfers the motion from the slider-crank to the four-bar. A tool-holder is mechanically fixed to the link CD and defines the offset towards the point P, which is the intended primary location for the RCM of the tool.

Since a four-bar mechanism **cannot provide a mechanically enforced RCM**, the point P shifts as the tool tilts. However, this motion can be actively compensated using the delta robot's degrees of freedom, thereby enabling a virtual RCM (**V-RCM**) despite the lack of a mechanically enforced pivot.

3 Four-Bar Linkage Mechanism

Figure 2: Side view of the tilt mechanism

3.1 Forward Kinematics

For the forward kinematics of this four-bar mechanism, the input is the linear actuator stroke length s , and the output is the tool angle θ_{tool} . Due to the nature of the four-bar linkage, the motion of the tool involves both rotation and translation. However, these two motions are kinematically coupled — knowing one uniquely determines the other.

The forward kinematics is relatively straightforward to compute since the lengths of all the links are known. Link AB is fixed in space, and point P maintains a fixed position relative to link CD. For simplicity, we define point A as the origin of the coordinate system. As the stroke length $s \in [0, 50]$ is known:

$$x_{AR} = x_{AR_{max}} - s \quad (1)$$

where $x_{AR_{max}}$ is the max horizontal distance between the origin to the slider, which is known based on the design parameter, and y_{AR} is also a fixed value, representing the height from the linear guide rail to the frame $\{a\}$.

Thus,

$$L_{AR} = \sqrt{x_{AR}^2 + y_{AR}^2} \quad (2)$$

$$\alpha_4 = \arctan(y_{AR}, x_{AR}) \quad (3)$$

As the lengths of AQ and QR are known, we can get α_3 from the law of cosine:

$$\alpha_3 = \arccos\left(\frac{L_{AR}^2 + L_{AQ}^2 - L_{QR}^2}{2L_{AR}L_{AQ}}\right) \quad (4)$$

Since ϕ_1 and ϕ_2 are angles with fixed values, and α_3, α_4 are known:

$$\theta_1 = 180^\circ - (\phi_2 + \alpha_3 + \alpha_4) \quad (5)$$

$$\alpha_1 = \phi_1 - \theta_1 \quad (6)$$

Form the law of cosine again:

$$L_{BD} = \sqrt{L_{AB}^2 + L_{DA}^2 - 2L_{AB}L_{DA}\cos(\alpha_1)} \quad (7)$$

$$\beta_1 = \arccos\left(\frac{L_{AB}^2 + L_{BD}^2 - L_{DA}^2}{2L_{AB}L_{BD}}\right) \quad (8)$$

$$\delta = \arccos\left(\frac{L_{BD}^2 + L_{CD}^2 - L_{BC}^2}{2L_{BD}L_{CD}}\right) \quad (9)$$

$$\theta_2 = 180^\circ - ((180^\circ - \beta_1 - \phi_1) + \delta) = \beta_1 + \phi_1 - \delta \quad (10)$$

Since ϕ_3 and ϕ_4 are also known:

$$\theta_{tool} = 180^\circ - \phi_4 - (\phi_3 - \theta_2) \quad (11)$$

As the lengths of AD and DP are constants, the x and y coordinates of point \mathbf{P} in frame $\{a\}$ can be directly computed:

$$P_x = \cos(\theta_1)L_{DA} + \cos(\theta_2 - \phi_3)L_{DP} \quad (12)$$

$$P_y = \sin(\theta_1)L_{DA} + \sin(\theta_2 - \phi_3)L_{DP} \quad (13)$$

To express the transformation matrix from coordinate frame $\{a\}$ to $\{t\}$, we can adopt a simplified approach by modeling links AD and DP as a 2-DOF serial robotic arm, but it is important to note that the joint angles in this representation are not independent.

Let $\theta = 90^\circ - \phi_4 - (\phi_3 - \theta_2)$, the angle between the x-axis of frame $\{a\}$ and the x-axis of frame $\{t\}$:

$$T_{at} = \begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 & P_x \\ \sin(\theta) & \cos(\theta) & 0 & P_y \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (14)$$

Thus, given the stroke length s , we can then determine both the tool's tilt angle and its position relative to frame $\{a\}$.

3.2 Inverse Kinematics

The inverse kinematics of this mechanism is somewhat more complex. Given the tool's tilt angle θ_{tool} , we can determine θ_2 . However, if you substitute θ_2 back to the eq.(10) to compute θ_1 , you will find that both β_1 and δ are unknown since the length of BD is also unknown. Solving for these variables would require handling a set of quadratic equations, which can be computationally expensive.

Thus, a more efficient approach is to derive the inverse kinematics directly from the geometry of the four-bar linkage. By translating edges AB and BC to form a new quadrilateral ABCE, as shown in Fig.(3):

Figure 3: Close up of the four-bar mechanism

The goal is to determine the stroke length s given the value of θ_2 :

We know that $L_{CE} = L_{AB}$, $L_{AE} = L_{BC}$, $\angle CEG = \phi_1$

$$L_{DF} = \cos(\theta_2)L_{CD} - \cos(\phi_1)L_{AB} \quad (15)$$

$$L_{EF} = \sin(\phi_1)L_{AB} - \sin(\theta_2)L_{CD} \quad (16)$$

$$L_{DE} = \sqrt{L_{DF}^2 + L_{EF}^2} \quad (17)$$

Given the lengths of AD, AE, and DE, using the law of cosine:

$$\angle ADH = \arccos\left(\frac{L_{AD}^2 + L_{DE}^2 - L_{AE}^2}{2L_{AD}L_{DE}}\right) \quad (18)$$

$$\angle AHD = \angle FDH = \arctan(L_{EF}, L_{DF}) \quad (19)$$

$$\theta_1 = 180^\circ - \angle ADH - \angle AHD \quad (20)$$

Then, we can use θ_1 to calculate the stroke length s .

Let $\alpha = \alpha_3 + \alpha_4$:

$$\alpha = 180^\circ - \theta_1 - \phi_2 \quad (21)$$

$$x_{AR} = \cos(\alpha)L_{AQ} + \sqrt{L_{QR}^2 - (\sin(\alpha)L_{AQ} - y_{AR})^2} \quad (22)$$

$$s = x_{AR_{max}} - x_{AR} \quad (23)$$

3.3 Tool Tip Velocity

Calculating the tool tip velocity relative to frame $\{a\}$ can also be quite challenging. If you attempt to take the time derivatives of eq.(12) and eq.(13), you'll find the expressions of $\dot{\theta}_1$ and $\dot{\theta}_2$ are very messy because you need to take derivative of arctan and arccos functions, and the final expressions become unwieldy and difficult to interpret.

To address this, I use a technique known as the **Instantaneous Center of Velocity** method to make the expressions of $\dot{\theta}_1$ and $\dot{\theta}_2$ short and clear. If you've taken a course in mechanisms or dynamics, you may already be familiar with it. If not, the basic idea is that at any given instant, a rigid link in planar motion can be treated as rotating about a specific point in space, known as the instantaneous center. In our case, these points are labeled as **I** and **J**, as illustrated in Fig.(4).

Figure 4: Velocity analysis for four-bar link and crank slider mechanism

For example, at any instant, link **QR** can be assumed to be in pure rotation with respect to the point **J**, where **QJ** is perpendicular to the velocity of point **Q** and **RJ** is perpendicular to the velocity of point **R**.

Then, we can get:

$$L_{JR} = \tan(\alpha) \cdot x_{AR} - y_{AR} \quad (24)$$

$$L_{JQ} = \sec(\alpha) \cdot x_{AR} - L_{AQ} \quad (25)$$

$$\dot{\rho} = \frac{\dot{s}}{L_{JR}} \quad (26)$$

$$L_{AQ} \cdot \dot{\alpha} = -L_{JQ} \cdot \dot{\rho} \quad (27)$$

$$\dot{\theta}_1 = \dot{\alpha} = -\frac{L_{JQ}}{L_{AQ}} \dot{\rho} \quad (28)$$

After determined $\dot{\theta}_1$, we want to find $\dot{\theta}_2$ and corresponding linear velocities \dot{P}_x and \dot{P}_y .

Similarly, link **CD** can be assumed to be in pure rotation with respect to the point **I**, where **CI** is perpendicular to the velocity of point **C** and **DI** is perpendicular to the velocity of point **D**.

$$\beta_2 = \arccos\left(\frac{L_{BC}^2 + L_{BD}^2 - L_{CD}^2}{2L_{BC}L_{BD}}\right) \quad (29)$$

Let $\beta = \beta_1 + \beta_2$:

$$\angle AIB = 180^\circ - \alpha_1 - \beta \quad (30)$$

Then, apply the law of sine:

$$\frac{L_{AB}}{\sin(\angle AIB)} = \frac{L_{IA}}{\sin(\beta)} = \frac{L_{IB}}{\sin(\alpha_1)} \quad (31)$$

Since $\sin(180^\circ - \alpha_1 - \beta) = \sin(\alpha_1 + \beta)$:

$$L_{IA} = \frac{L_{AB} \cdot \sin(\beta)}{\sin(\alpha_1 + \beta)} \quad (32)$$

$$L_{ID} = L_{IA} - L_{DA} \quad (33)$$

Using Instantaneous Center method:

$$\dot{\theta}_1 L_{DA} = -\dot{\theta}_2 L_{ID} \quad (34)$$

$$\dot{\theta}_{tool} = \dot{\theta}_2 = -\frac{L_{DA}}{L_{ID}} \dot{\theta}_1 \quad (35)$$

From eq.(28) and eq.(26), we can get:

$$\dot{\theta}_{tool} = \frac{L_{DA} L_{JQ}}{L_{ID} L_{AQ} L_{JR}} \dot{s} \quad (36)$$

Noted that $L_{JQ}(s)$, $L_{ID}(s)$, and $L_{JR}(s)$ are not constants.

Thus eq.(36) has the form of: $\dot{\theta}_{tool} = f(s)\dot{s}$

Then, taking derivative to eq.(12) and eq.(13), we can get the linear velocity of the tool tip:

$$\dot{P}_x = -\sin(\theta_1)L_{DA}\dot{\theta}_1 - \sin(\theta_2 - \phi_3)L_{DP}\dot{\theta}_2 \quad (37)$$

$$\dot{P}_y = \cos(\theta_1)L_{DA}\dot{\theta}_1 + \cos(\theta_2 - \phi_3)L_{DP}\dot{\theta}_2 \quad (38)$$

where

$$\dot{\theta}_1 = -\frac{L_{JQ}}{L_{AQ}L_{JR}}\dot{s} \quad (39)$$

$$\dot{\theta}_2 = \frac{L_{DA}L_{JQ}}{L_{ID}L_{AQ}L_{JR}}\dot{s} \quad (40)$$

We now obtain a clear and compact expression for the velocity of point **P**.

4 Roll Mechanism

Figure 5: Kinematics diagram of the frames of SHER-3.0

The roll mechanism is relatively straightforward. As illustrated in Fig.(5), the roll angle ψ is defined with respect to the z-axis of frame $\{p\}$, and the rotational velocity $\dot{\psi}$ is directly controlled by the motor, with the positive direction defined along the x-axis of the base frame $\{b\}$. The roll axis is located d_1 mm above the delta platform $\{p\}$, and frame $\{a\}$ is positioned d_3 mm above along the z-axis of frame $\{r\}$.

However, it is important to note that the orientations of frames $\{a\}$ and $\{r\}$ are different. In the home configuration, the vertical axis of frame $\{a\}$ is y-axis, whereas the vertical axis of frame $\{r\}$ is z-axis. Additional geometric details and frame assignments are shown in Fig.(6).

5 Tool Tip Velocity in Delta Platform Frame

Figure 6: Front view of frames $\{p\}$, $\{r\}$, $\{a\}$ of SHER-3.0

Recall that all previous kinematic derivations for the tool tip were expressed in frame $\{a\}$. To express the tool tip velocity in the delta platform frame $\{p\}$, we need to apply the following coordinate transformations:

First, define the homogeneous transformation matrix T_{pr} , which represents the transformation from frame $\{p\}$ to frame $\{r\}$:

$$T_{pr} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(\psi) & -\sin(\psi) & 0 \\ 0 & \sin(\psi) & \cos(\psi) & d_1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (41)$$

Similarly, define the homogeneous transformation matrix T_{ra} , which represents the transformation from frame $\{r\}$ to frame $\{a\}$:

$$T_{ra} = \begin{bmatrix} 1 & 0 & 0 & d_2 \\ 0 & \cos(90^\circ) & -\sin(90^\circ) & 0 \\ 0 & \sin(90^\circ) & \cos(90^\circ) & d_3 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (42)$$

Then, by multiplying the two matrices, we obtain the transformation matrix T_{pa} :

$$T_{pa} = T_{pr}T_{ra} = \begin{bmatrix} 1 & 0 & 0 & d_2 \\ 0 & -\sin(\psi) & -\cos(\psi) & -\sin(\psi)d_3 \\ 0 & \cos(\psi) & -\sin(\psi) & \cos(\psi)d_3 + d_1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (43)$$

Given the tool tip position \mathbf{P} expressed in frame $\{a\}$ as $\mathbf{P}_{\{a\}}$, we can compute its coordinates in frame $\{p\}$, denoted as $\mathbf{P}_{\{p\}} = T_{pa}\mathbf{P}_{\{a\}}$:

Since the four-bar linkage is a planar mechanism, the z-component of the tool tip position in frame $\{a\}$, $P_{z\{a\}}$ is always zero.

$$\begin{bmatrix} P_{x\{p\}} \\ P_{y\{p\}} \\ P_{z\{p\}} \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & d_2 \\ 0 & -\sin(\psi) & -\cos(\psi) & -\sin(\psi)d_3 \\ 0 & \cos(\psi) & -\sin(\psi) & \cos(\psi)d_3 + d_1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} P_{x\{a\}} \\ P_{y\{a\}} \\ 0 \\ 1 \end{bmatrix} \quad (44)$$

$$\begin{bmatrix} P_{x\{p\}} \\ P_{y\{p\}} \\ P_{z\{p\}} \end{bmatrix} = \begin{bmatrix} P_{x\{a\}} + d_2 \\ -\sin(\psi)P_{y\{a\}} - \sin(\psi)d_3 \\ \cos(\psi)P_{y\{a\}} + \cos(\psi)d_3 + d_1 \end{bmatrix} \quad (45)$$

By taking the time derivative of eq.(45), we obtain the expression for the tool tip velocity in frame $\{p\}$:

$$\begin{bmatrix} \dot{P}_{x\{p\}} \\ \dot{P}_{y\{p\}} \\ \dot{P}_{z\{p\}} \end{bmatrix} = \begin{bmatrix} \dot{P}_{x\{a\}} \\ -\sin(\psi)\dot{P}_{y\{a\}} - \cos(\psi)\dot{\psi}(P_{y\{a\}} + d_3) \\ \cos(\psi)\dot{P}_{y\{a\}} - \sin(\psi)\dot{\psi}(P_{y\{a\}} + d_3) \end{bmatrix} \quad (46)$$

For the angular velocity, the components can be easily identified:

$$\begin{bmatrix} \dot{\theta}_{x\{p\}} \\ \dot{\theta}_{y\{p\}} \\ \dot{\theta}_{z\{p\}} \end{bmatrix} = \begin{bmatrix} \dot{\psi} \\ -\cos(\psi)\dot{\theta}_2 \\ -\sin(\psi)\dot{\theta}_2 \end{bmatrix} \quad (47)$$

where $\dot{\psi}$ is the roll velocity and $\dot{\theta}_2$ is the tilt velocity.

Thus, we can express the tool tip velocity in frame $\{p\}$ as:

$$\begin{bmatrix} \dot{P}_x \\ \dot{P}_y \\ \dot{P}_z \\ \dot{\theta}_x \\ \dot{\theta}_y \\ \dot{\theta}_z \end{bmatrix}_{\{p\}} = \begin{bmatrix} \dot{P}_{x\{a\}} \\ -\sin(\psi)\dot{P}_{y\{a\}} - \cos(\psi)\dot{\psi}(P_{y\{a\}} + d_3) \\ \cos(\psi)\dot{P}_{y\{a\}} - \sin(\psi)\dot{\psi}(P_{y\{a\}} + d_3) \\ \dot{\psi} \\ -\cos(\psi)\dot{\theta}_2 \\ -\sin(\psi)\dot{\theta}_2 \end{bmatrix} \quad (48)$$

where

$$\begin{aligned} \dot{P}_{x\{a\}} &= -\sin(\theta_1)L_{DA}\dot{\theta}_1 - \sin(\theta_2 - \phi_3)L_{DP}\dot{\theta}_2 \\ \dot{P}_{y\{a\}} &= \cos(\theta_1)L_{DA}\dot{\theta}_1 + \cos(\theta_2 - \phi_3)L_{DP}\dot{\theta}_2 \\ P_{y\{a\}} &= \sin(\theta_1)L_{DA} + \sin(\theta_2 - \phi_3)L_{DP} \\ \dot{\theta}_2 &= \frac{L_{DA}L_{JQ}}{L_{ID}L_{AQ}L_{JR}}\dot{s} \end{aligned} \quad (49)$$

6 Kinematics Simulation and Visualization

The visualization script is available at https://github.com/zhaob5/roll_tilt_mechanism. This simple simulation only focuses on the four-bar linkage mechanism, with all coordinates defined in frame {a}. The tool tip velocity and trajectory are also visualized, currently limited to 2-D planar space. Feel free to follow the page for updates or contribute if you're interested.

Figure 7: Forward Kinematics Visualization

7 Disclaimer

The calculations and methods presented in this document are based on my personal understanding and interpretation of the roll and tilt mechanism of SHER-3.0. I hope the derivations provide useful insights and inspiration for your own work. Please note that if you define coordinate frames or the home configuration differently than described here, your results may differ. Therefore, it is more important to understand the principles of the derivation than to directly copy the final expressions into your work. While I've made every effort to ensure accuracy, there may still be errors or oversights. I strongly encourage you to verify the results independently before applying them in any critical context. If you have suggestions, corrections, or would like to discuss the topic further, feel free to reach out to me at: bzhao17@alumni.jh.edu.
